to-date user interface tools that you have come to expect from the OpenCRT client. It's free and open source, and you can download it from the projects' site. The security and privacy of data are at the forefront of most organizations' information security strategies. Many organizations realize that secure transmission of data is a critical part of their overall information security programs and policies.

Encryption is a critical part of that equation. So is the ability to handle the authentication of users, which means you need to be able to easily generate and manage user IDs and passwords. The use of encryption to protect sensitive information is supported by standards such as the Data Security Standard (DSS) published by the National Institute of Standards and Technology (NIST). From an information security standpoint, NIST defines encryption as a mechanism for transforming information from an intelligible form to an unintelligible form. Encryption is a crucial step in the chain of steps required to make information secure—but it's not a standalone solution. You need to provide a means to authenticate the individuals and devices that are accessing the protected data. The best authentication method for your organization is the one that will not let anything but authorized personnel access the data. In other words, you need to provide the best user authentication solution—one that isn't just good, but that also works. You need a solution that provides strong authentication, integrity, and confidentiality for the encryption used to protect the data. Server-Based Authentication When you generate a user ID or a password, you create a standard account on the system that is to be protected. That standard account can then be used to manage other user accounts. For instance, if you're using the OpenCRT client on a Windows system, and you're going to create a new user account, you'll want to use that user's standard account. And when you are prompted to enter a user name, you can enter that standard user name. The benefit of using a standard account is that the standard account is protected by the system's authentication mechanisms, which means that you don't have to remember a long user name and password to protect access to the data on the system. You only have to remember the standard user name and password you used to create the standard account. In fact, most of the time, all you need to remember is the standard user name you used to 82157476af
